Section 1

Motivation

< □ ▶ < @ ▶ < \ = ▶ < \ = - つへで 2/26

Introduction: Topic Models

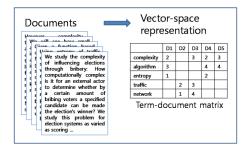

- Challenge
 - given: corpus of text documents (e.g. web pages)
 - goal: find low-dimensional document representation in semantic space of topics or concepts – aboutness of documents
 - also known as topic models
- Approach: predictive model
 - log-liklihood of predicting words in document
 - MLE: probabilistic Latent Semantic Analysis (pLSA)
 - Bayesian: Latent Dirichlet Allocation (LDA)
 - related to non-negative matrix decomposition

Document Representation: Pre-Processing

- Vocabulary
 - ▶ all "meaningful" words (=terms) in a language
 - extracted from corpus documents via tokenization
 - ▶ large cardinality (e.g. ~1-100 million)
- Term filtering
 - exclude stop words ("the", "is", "at", "which", etc.).
 - exclude infrequent words, misspellings, tokenizer errors, etc.
- Term normalization
 - stemming (optionally): reduce word to stem/lemma
 - example: "argue", "argued", "argues", "arguing", and "argus" reduce to the stem "arg"

Document Representation: Bag-of-Words

- Bag-of-word Representation
 - ignore order of words in sentences/document
 - reduce data to co-occurrence counts
 - see previous lecture: word context = entire document
 - document = M-dimensional vector of counts, very sparse!

Section 2

Probabilistic LSA

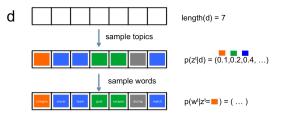

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Probabilistic LSA: Topic Model

- Topic parameters = word distribution
- Document = mixture of topics
 - \neq probabilistic assignment
 - example: document on soccer world cup 2022 in Dubai
 - soccer vocabulary (e.g. "teams", "play", "soccer", "match")
 - political vocabulary (e.g. "labor", "corruption", "president")
 - mixing weights \neq uncertainty about correct topic
- ► Goal: Discover topics in an unsupervised fashion.

Probabilistic LSA: Two-Stage Sampling

- Two-stage (hierarchical) sampling:
 - (1) sample topic for each token
 - (2) sample token, given sampled topic
- Model parameters
 - each document = specific mix of topics (colors): p(z|d)
 - each topic (color) = specific distribution of words: p(w|z)

Probabilistic LSA: Basic Model

Context model:

occurrence of word w in context/document d

$$p(w|d) = \sum_{z=1}^{K} p(w|z)p(z|d)$$

- identify topics with integers $z \in \{1, \ldots, K\}$ (K: pre-specified)
- relative to a fixed "slot" (i.e. fixed position in document)
- identical distribution for every slot
- Conditional independence assumption (*)

$$p(w|d) = \sum_{z} p(w, z|d) = \sum_{z} p(w|d, z) p(z|d) \stackrel{*}{=} \sum_{z} p(w|z) p(z|d)$$

topics represent regularities common to the entire collection

Probabilistic LSA: Log-Likelihood

- Summarize data into co-occurrence counts X = x_{ij} (# occurrences of w_j in document d_i)
- Alternatively: multiset \mathcal{X} over index pairs (i, j)

Log-likelihood

$$\ell(\mathbf{U}, \mathbf{V}) = \sum_{i,j} x_{ij} \log p(w_j | d_i) = \sum_{(i,j) \in \mathcal{X}} \log \sum_{z=1}^{K} \underbrace{p(w_j | z)}_{=: v_{zi}} \underbrace{p(z | d_i)}_{=: u_{zi}}$$

- two types of parameters:
- $u_{zi} \ge 0$ such that $\sum_{z} u_{zi} = 1 \; (\forall i)$
- $v_{zj} \ge 0$ such that $\sum_j v_{zj} = 1 \; (\forall z)$

Expectation Maximization for pLSA

- Missing data $Q_{zij} \in \{0,1\}$: w_j in d_i generated via z, $\sum_z Q_{zij} = 1$
- ▶ Variational parameters $q_{zij} = \Pr(Q_{zij} = 1)$, $\sum_{z} q_{zij} = 1$
- Lower bound from Jensen's inequality

$$\log \sum_{z=1}^{K} q_{zij} \frac{u_{zi} v_{zj}}{q_{zij}} \ge \sum_{z=1}^{K} q_{zij} \left[\log u_{zi} + \log v_{zj} - \log q_{zij} \right]$$

Solve for optimal q (Expectation Step)

$$q_{zij} = \frac{u_{zi}v_{zj}}{\sum_{k=1}^{K} u_{ki}v_{kj}} = \frac{p(w_j|z)p(z|d_i)}{\sum_{k=1}^{K} p(w_j|k)p(k|d_i)}$$

<□ ▶ < □ ▶ < ■ ▶ < ■ ▶ < ■ ▶ ■ 9 Q (P 11/26

$$\blacktriangleright \implies$$
 posterior of Q_{zij} under model

Expectation Maximization for pLSA (cont'd)

Solve for optimal parameters (Maximization Step)

$$u_{zi} = \frac{\sum_j x_{ij} q_{zij}}{\sum_j x_{ij}}, \qquad v_{zj} = \frac{\sum_i x_{ij} q_{zij}}{\sum_{i,l} x_{il} q_{zil}},$$

< □ > < @ > < E > < E > E の < ○ 12/26

- numerator: simple weighted counts
- denominator: ensure proper normalization
- EM for MLE in pLSA ;-)
 - guaranteed convergence (cf. mixture models)
 - not guaranteed to find global optimum

Topics Discovered by pLSA

Table: Eight selected topics from a 128 topic decomposition. The displayed word stems are the 10 most probable words in the class-conditional distribution p(word|topic), from top to bottom in descending order.

Hofmann, Thomas. Probabilistic latent semantic indexing. ACM SIGIR Forum. Vol. 51. No. 2. ACM, 2017. (re-print from 1999)

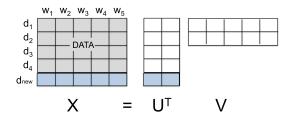

Section 3

Latent Dirichlet Allocation

< □ ▶ < □ ▶ < ∃ ▶ < ∃ ▶ < ∃ ▶ E の Q @ 14/26

Generative Document Model

- Probabilistic LSA: both dimensions of matrix are fixed
- Generative document model: how to sample new document?
- Co-occurrence matrix: how to sample additional row of X?

- Need to be able to sample topic weights u_i = (u_{1i},..., u_{Ki})[⊤] for a new document
- \blacktriangleright Combine with existing V to predict new data row

Latent Dirichlet Allocation (LDA)

u_i is a probability vector, "simplest" (conjugate) distribution =
Dirichlet distribution

$$p(\mathbf{u}_i|\alpha) \propto \prod_{z=1}^{K} u_{zi}^{\alpha_z - 1}$$

- given α parameters (K dim.), can generate topic weights
- but, we can do more ...
- Bayesian view: treat U as nuisance parameters
 - ▶ U needs to be averaged out
 - \blacktriangleright V are real parameters, U can be re-constructed, if needed
 - advantages in terms of model averaging

Latent Dirichlet Allocation: Bayesian View

- ▶ LDA model (fixed document length $l = \sum_j x_j$)
 - multinomial observation model (x = word count vector)

$$p(\mathbf{x}|\mathbf{V},\mathbf{u}) = \frac{l!}{\prod_j x_j!} \prod_j \pi_j^{x_j}, \quad \pi_j := \sum_z v_{zj} u_z$$

Bayesian averaging over u

$$p(\mathbf{x}|\mathbf{V},\alpha) = \int p(\mathbf{x}|\mathbf{V},\mathbf{u}) p(\mathbf{u}|\alpha) \, d\mathbf{u}$$

- Generative model
 - for each d_i : sample $\mathbf{u}_i \sim \mathsf{Dirichlet}(\alpha) \Longrightarrow \mathsf{integrate}$ out
 - ▶ for each word slots w^t , $1 \le t \le l_i \Longrightarrow iid_{\cdot} = product$
 - sample topic $z^t \sim \mathsf{Multi}(\mathbf{u}_i) \Longrightarrow \mathsf{latent}$, sum out
 - then sample $w^t \sim \mathsf{Multi}(\mathbf{v}_{z^t}) \Longrightarrow \mathsf{observable}$

Latent Dirichlet Allocation: Algorithms

Learning algorithms

- variational expectation maximization
- Markov Chain Monte Carlo (MCMC): collapsed Gibbs sampling
- distributed, large-scale implementations (100Ms of documents)
- (beyond the scope of this lecture...)

Blei, David M., Andrew Y. Ng, and Michael I. Jordan. "Latent dirichlet allocation." Journal of Machine Learning Research, 2003, pp. 993-1022.

◆□▶ < @ ▶ < E ▶ < E ▶ E りへで 18/26</p>

Latent Dirichlet Allocation: Examples

Figure 1. The initiations behind latent Dirichlet allocation. We assume that some number of "topics," which are distributions over drives exist for the whole collection (for fell). Each document is assumed to be generated as follows: First choose a distribution over the topics thin histogram at right; then, for each word, choose a topic assignment (the colored conis) and choose the word from the corresponding topic. The topics and topic assignments in this figure are illustrative—they are not fift from real data. See Figure 2 for topics if from data.

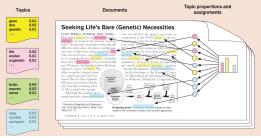

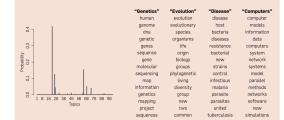

Figure 2. Real inference with LDA. We fit a 100-topic LDA model to 17,000 articles from the journal Science. At left are the inferred topic proportions for the example article in Figure 1. At right are the top 15 most frequent words from the most frequent topics found in this article.

Example from Blei, 2012

Section 4

Non-Negative Matrix Factorization

< □ ▶ < □ ▶ < Ξ ▶ < Ξ ▶ Ξ · ⑦ Q @ 20/26

Non-Negative Matrix Factorization

• Count matrix
$$\mathbf{X} \in \mathbb{Z}_{\geq 0}^{N \times M}$$

Non-negative matrix factorization (NMF) of X:

$$\mathbf{X} \approx \mathbf{U}^{\top} \mathbf{V}, \quad x_{ij} = \sum_{z} u_{zi} v_{zj} = \langle \mathbf{u}_i, \mathbf{v}_j \rangle$$

<□ ▶ < □ ▶ < ■ ▶ < ■ ▶ < ■ ▶ ■ 9 Q C 21/26

- \blacktriangleright constraints on matrix factors ${\bf U}$ and ${\bf V}$
 - non-negativity as all parameters are probabilities
 - normalization U, V are L₁ column-normalized
- approximation quality measured via log-likelihood
- dimension reduction: $N \cdot M \gg (N+M)K N M$

NMF for Quadratic Cost Function

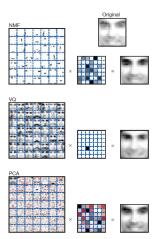

- pLSA: just one instance of a non-negative matrix factorization
- Variation: non-negative data X with quadratic cost function = non-negative matrix approximation

$$\begin{split} \min_{\mathbf{U},\mathbf{V}} \quad J(\mathbf{U},\mathbf{V}) &= \frac{1}{2} \|\mathbf{X} - \mathbf{U}^{\top}\mathbf{V}\|_{F}^{2}. \\ \text{s.t.} \quad u_{zi}, v_{zj} \geq 0 \quad (\forall i,j,z) \quad (\text{non-negativity}) \end{split}$$

- Similar as pLSA, but ...
 - different sampling model: Gaussian vs. multinomial
 - different objective: quadratic instead of KL divergence
 - different constraints (not normalized)

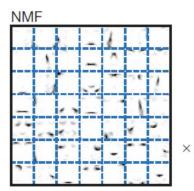

Part-Based Representation of Faces

- NMF is useful when modelling non-negative data (e.g. images = non-negative intensities)
- Additive superpositions without cancellations => NMF leads to part-based representations
- vs. vector quantization, K-means: combination of multiple basis images

D.D. Lee & H. S. Seung, Learning the parts of objects by non-negative matrix factorization, Nature, 40, 1999.

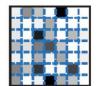

Part-Based Representation of Faces (zoom-in)

=

NMF Algorithm: Quadratic Costs

- Alternating least squares
 - \blacktriangleright convex in ${\bf U}$ given ${\bf V}$ and vice versa, but not jointly in $({\bf U},{\bf V})$
 - ${\scriptstyle \blacktriangleright}\,$ \Rightarrow alternate optimization of ${\bf U}$ and ${\bf V}$, keeping the other fixed
 - normal equations in matrix notation

 $(\mathbf{U}\mathbf{U}^{\top})\mathbf{V} = \mathbf{U}\mathbf{X}, \text{ and } (\mathbf{V}\mathbf{V}^{\top})\mathbf{U} = \mathbf{V}\mathbf{X}^{\top}$

- solved via QR-decomposition or gradient descent
- project in between alternations non-negativity!

$$u_{zi} = \max\{0, u_{zi}\}, \quad v_{zj} = \max\{0, v_{zj}\}$$

More detailed discussion of algorithms for NMF see:

Berry, M.W. et al.: Algorithms and applications for approximate nonnegative matrix factorization. Computational Statistics & Data Analysis, 52(1), 2007, pp.155-173.

pLSA & NMF: Discussion

 Matrix factorization obeying non-negativity and (optionally, pLSA) normalization constraints

< □ > < @ > < E > < E > E の < ○ 26/26

- Different cost functions: multinomial likelihood, quadratic loss
- Iterative optimization (EM algorithm, projected ALS)
- Interpretability of factors: topics, parts, etc.
- Wide range of applications
